## Comparing within-subject variances in a study to compare two methods of measurement

Martin Bland, 22 April, 2001
In the design for comparing two methods of measurement proposed by Bland and Altman (1986), two observations are made by each method on each subject. This design was use to compare a Wright peak flow meter and a min Wright peak flow meter. The following measurements of peak expiratory flow (litres $/ \mathrm{min}$ ) were obtained:

| Subject | Wright | meter | Mini | meter |
| :---: | :---: | :---: | :---: | :---: |
|  | Obs 1 | Obs 2 | Obs 1 | Obs 2 |
| 1 | 494 | 490 | 512 | 525 |
| 2 | 395 | 397 | 430 | 415 |
| 3 | 516 | 512 | 520 | 508 |
| 4 | 434 | 401 | 428 | 444 |
| 5 | 476 | 470 | 500 | 500 |
| 6 | 557 | 611 | 600 | 625 |
| 7 | 413 | 415 | 364 | 460 |
| 8 | 442 | 431 | 380 | 390 |
| 9 | 650 | 638 | 658 | 642 |
| 10 | 433 | 429 | 445 | 432 |
| 11 | 417 | 420 | 432 | 420 |
| 12 | 656 | 633 | 626 | 605 |
| 13 | 267 | 275 | 260 | 227 |
| 14 | 478 | 492 | 477 | 467 |
| 15 | 178 | 165 | 259 | 268 |
| 16 | 423 | 372 | 350 | 370 |
| 17 | 427 | 421 | 451 | 443 |

We recommended that the repeatability should be calculated for each method separately and compared. I was recently asked how we could carry out a statistical comparison of the two repeatabilities.

The problem is how to compare the within-subject standard deviations in a matched sample.
Denote the pairs of measurements by the same method on subject $i$ by $x_{i}$ and $y_{i}$. The standard deviation for a single subject $s_{i}$ is given by the following formula for variance, i.e. standard devation squared:

$$
\begin{aligned}
s_{i}^{2} & =\frac{1}{2-1}\left(x_{i}^{2}+y_{i}^{2}-\frac{\left(x_{i}+y_{i}\right)^{2}}{2}\right) \\
& =\frac{x_{i}^{2}}{2}+\frac{y_{i}^{2}}{2}-x_{i} y_{i} \\
& =\frac{1}{2}\left(x_{i}-y_{i}\right)^{2}
\end{aligned}
$$

Hence for each subject the squared difference $\left(x_{i}-y_{i}\right)^{2}$ is an estimate of the within-subject variance for that method of measurement times 2 , and the absolute value $\left|x_{i}-y_{i}\right|$ is an estimate of the within-subject standard deviation for that method of measurement times root 2 . We can compare these estimates between the two methods of measurement using the two sample $t$ method. It is usually preferable to compare variances rather than to compare standard deviations directly.

For the PEFR meter data, the squared differences are:

| Subject | Wright meter | Mini meter |
| :---: | :---: | :---: |
| 1 | 16 | 169 |
| 2 | 4 | 225 |
| 3 | 16 | 144 |
| 4 | 1089 | 256 |
| 5 | 36 | 0 |
| 6 | 2916 | 625 |
| 7 | 4 | 9216 |
| 8 | 121 | 100 |
| 9 | 144 | 256 |
| 10 | 16 | 169 |
| 11 | 9 | 144 |
| 12 | 529 | 441 |
| 13 | 64 | 1089 |
| 14 | 196 | 100 |
| 15 | 169 | 81 |
| 16 | 2601 | 400 |
| 17 | 36 | 64 |

For the paired t method, the differences between the squared differences by the two methods should follow a Normal distribution and be unrelated to the average squared difference for the subject. This is clearly not the case here, as the graph shows:

The assumptions of the paired $t$ method a re clearly not met in this case and I suspect that this will always be so. A log transformation of the squared differences is quite effective:

One of the differences for the Wright meter was zero. It was replaced by half the next smallest value, 64 , for this analysis.

Proceeding with the paired t test (Stata output) we get:

```
One-sample t test Number of obs = N 17
```

```
Degrees of freedom: 16
```

Thus in the example there is only very weak evidence that there is a difference between the within-subject variances. Antilogging the mean difference we get $\exp (1.098972)=3.00$, showing that the within-subject variance for the mini meter is estimated to be 3 times that for the Wright meter, but there is a very wide confidence interval for this ratio, from $\exp (-0.1671547)=$ 0.85 to $\exp (2.365098)=10.65$.

The square root of the ratio of within-subject variances will be the ratio of the within-subject standard deviations for the two methods of measurement.
